

I-V Characteristic (Luminarit-GreenRAM V2.1)

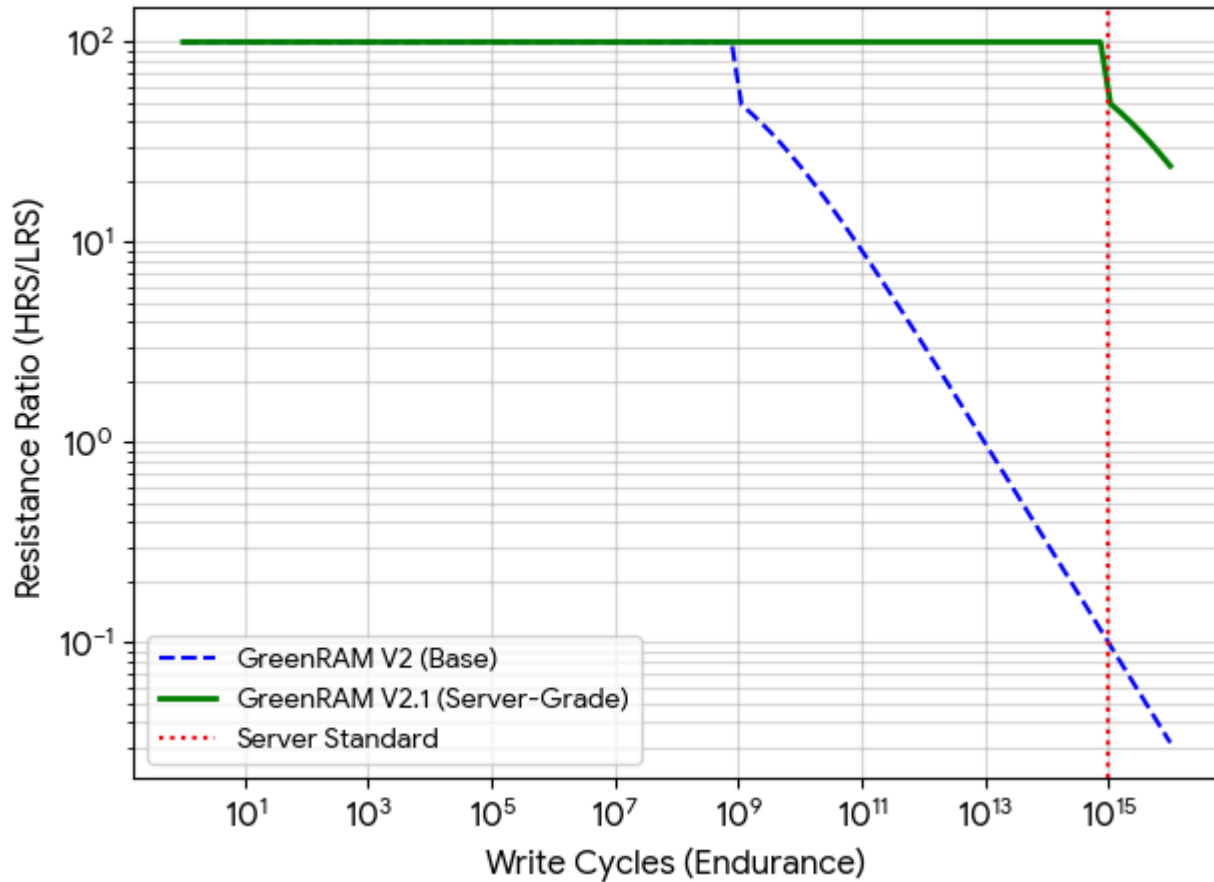

Energy Consumption (1 Year Operation)

CO2 Lifecycle Model

Endurance Model & Long-term Stability

Extension Protocol: Luminarit-GreenRAM V2.1 (Server-Grade)

1. Specification: Interfacial Quantum-Stabilizer (IQS) & ALC

This module elevates Luminarit-GreenRAM to industrial server-grade standards, meeting data center requirements for reliability and continuous load.

1.1 Physical Structure: hBN-Graphene Superlattice

To achieve an endurance of 10^{15} cycles, the anode is designed as an atomic superlattice.

- **Materials:** Alternating layers of Graphene (conductor) and hexagonal Boron Nitride (hBN, atomic insulator/sieve).
- **Function:** Oxygen vacancies (ions) are precisely "parked" within the lattice gaps of the hBN during the switching process. This prevents structural degradation of the $HfO_2 : N$ switching layer.
- **Thermics:** hBN provides a thermal conductivity of approx. 400 W/mK, eliminating hotspots at the filament site.

1.2 Control: Inductive Resonance Feedback (IRF)

Integration of the quantum interface for real-time monitoring.

- **Mechanism:** Measurement of impedance changes via inductive resonance.
- **Pulse Shaping:** The pulse is adjusted in the picosecond range as soon as the target conductance is reached.
 - Set Pulse: $V(t) = V_0 \cdot e^{-t/\tau}$
 - Reset Pulse: $V(t) = V_{max} \cdot (1 - e^{-t/\tau})$

2. Manufacturing Parameters (65-90 nm DUV)

The process is fully CMOS-compatible and utilizes existing infrastructure:

1. **Backend-of-Line (BEOL):** Sequential ALD/CVD deposition of the superlattice (1-2 nm).
2. **Thermal Casing:** Connection to vertical Boron Nitride Nanotubes for lateral heat dissipation.

3. Performance Matrix

Parameter	GreenRAM V2 (Base)	GreenRAM V2.1 (Server)	Benchmark (DDR5)
Endurance	$\geq 10^9$ cycles	$\geq 10^{15}$ cycles	Practically unlimited
Latency (Read)	< 10 ns	< 5 ns	10-15 ns
Retention	10 years	> 20 years	0 s (Volatility)
Idle Power	0 W	0 W	High (Refresh required)
Rare Earths	0%	0%	Partially present

4. Logical Verification

Consistency is maintained by using material-identical structures (hBN) for both the cell anode and the thermal casing. The endurance scaling is achieved through precise pulse control (IRF) rather than material excess.
